

■ Debug

`Debug[expr]` evaluates *expr*, allowing you to stop at function calls and in control structures.

`Debug[expr, {f1, f2, ...}]` stops only in evaluation of the functions *f_i*.

The following actions are possible in `Debug`:

<code>inspect (i)</code>	inspect current state
<code>step (s)</code>	step through the execution of the current expression
<code>next (n)</code>	continue to the next expression (default action)
<code>continue (c)</code>	continue to the end of the current control structure
<code>finish (f)</code>	continue to the end of the whole computation
<code>abort (a)</code>	abort the computation

■ When you inspect the current state, you can look at the values of any objects. However, you cannot perform any operation which assigns values. ■ `Quit [ ]` or `Exit [ ]` exits the inspector. ■ See page 264. ■ See also: `On, $Ignore EOF`.
