

## ■ Format

`Format[expr]` prints as the formatted form of *expr*.

Assigning values to `Format[expr]` defines print forms for expressions.

`Format[expr, type]` gives a format of the specified type.

Standard format types are:

|                          |                                                               |
|--------------------------|---------------------------------------------------------------|
| <code>CForm</code>       | C language input form                                         |
| <code>FortranForm</code> | fortran input form                                            |
| <code>InputForm</code>   | one-dimensional form suitable for input to <i>Mathematica</i> |
| <code>OutputForm</code>  | two-dimensional mathematical form                             |
| <code>TeXForm</code>     | TeX input form                                                |
| <code>TextForm</code>    | textual form                                                  |

- You can add your own format types. ■ Example: `Format[s] := form` defines a special print form for a symbol *s*.
- `Format[f[...]] := form` defines a print form for a function *f*. ■ Definitions for `Format` are stored in the `PrintValue` of a symbol. ■ See page 273. ■ See also: `ToShortString`.
