

■ Infix

`Infix[f[e1, e2, ...]]` prints with $f[e_1, e_2, \dots]$ given in default infix form:

$e_1 \sim f \sim e_2 \sim f \sim e_3 \dots$

`Infix[expr, h]` prints with arguments separated by h : $e_1 \ h \ e_2 \ h \ e_3 \ \dots$

`Infix[expr, h, precedence, grouping]` can be used to specify how the output form should be parenthesized.

■ Precedence levels are specified by integers. In `OutputForm`, some precedence levels are:

$x \cdot y \cdot z$ 210

$x \ y \ z$ 150

$x + y + z$ 140

$x == y$ 130

$x = y$ 60

■ Possible grouping (associativity) specifications are:

`NonAssociative` not associative – always parenthesized

`None` always associative – never parenthesized

`Left` left associative (e.g. $(a/b)/c$)

`Right` right associative (e.g. $a \wedge (b \wedge c)$)
