

■ N

$\mathbb{N}[expr]$ gives the numerical value of $expr$.

$\mathbb{N}[expr, n]$ does computations to n -digit precision.

$\mathbb{N}[expr, n]$ performs computations to n -digit precision. Often, this will give a result to n -digit accuracy. Sometimes, however, precision will be lost during the computation. ■ $\mathbb{N}$ converts all numbers to `Real` form. ■ You can define numerical values of functions using $f /: \mathbb{N}[f[args]] := value$ and $f /: \mathbb{N}[f[args], n] := value$. ■ See pages 26 and 30.
