

■ Names

`Names["string"]` gives a list of the names of symbols which match the string.

`Names["string"]` gives the same list of names as `?string`. ■ In the string, you can use the metacharacters `*`, `**` and `@`, as described in the notes on `StringMatchQ`. ■ Notice that the symbols in the list returned by `Names` are always evaluated.

■ See page 306. ■ See also: `Information`, `Unique`, `ValueQ`.
