

■ Not

`!expr` is the logical not function. It gives `False` if `expr` is `True`, and `True` if it is `False`.

`Not` gives symbolic results when necessary, and applies various simplification rules to them. ■ You cannot use the notation `!expr` for `Not [expr]` if it appears at the very beginning of a line. In this case, `!expr` is interpreted as a shell escape.

■ See page 73. ■ See also: `LogicalExpand`
