

■ NumberQ

`NumberQ[expr]` gives `True` if *expr* is a number, and `False` otherwise.

`NumberQ[expr]` returns `False` unless *expr* is manifestly a number (i.e. has head `Complex`, `Integer`, `Rational` or `Real`).

- You can use `NumberQ[x] = True` to override the normal operation of `NumberQ`, and effectively define *x* to be an integer.
- See pages 230 and 326. ■ See also: `IntegerQ`, `TrueQ`.
