

■ Operate

`Operate[p, f[x, y]]` gives $p[f][x, y]$.

`Operate[p, expr, n]` applies p at level n in the head of $expr$.

Examples: `Operate[p, f[x, y]]` $\longrightarrow$ `p[f][x, y]`; `Operate[p, f[x][y][z], 1]` $\longrightarrow$ `p[f[x][y]][z]`;
`Operate[p, f[x][y][z], 2]` $\longrightarrow$ `p[f[x]][y][z]`. ■ `Operate[p, f[x]]` effectively applies the functional operator p to the function f . ■ `Operate` plays essentially the same role for heads of expressions as `Map` plays for elements. Note, however, that the level specification for `Operate` works differently than for `Map`. ■ See page 247. ■ See also: `HeadCompose`, `Through`.
