

■ PatternTest

$p?test$ is a pattern object that stands for any expression which matches p , and on which the application of $test$ gives `True`.

Any result for $test[pval]$ other than `True` is taken to signify failure. ■ Example: `_?NumberQ` represents a number of any type. The `_` matches any expression, and `?NumberQ` restricts to any expression which gives `True` on application of the number test `NumberQ`. ■ The operator `?` has a high precedence. Thus `_^_?t` is `_^(_?t)` not `(_^_)?t`. ■ See page 557.

■ See also: `Condition`.
