

■ SameQ

`SameQ`[$expr_1$, $expr_2$, ...] yields `True` if all the $expr_i$ are identical, and yields `False` otherwise.

`SameQ` requires exact correspondence between expressions, except that it considers `Real` numbers equal if their difference is less than the precision of either of them. ■ `SameQ`[2, 2.] gives `False`. ■ See page 259. ■ See also: `Equal`, `Order`.
