

■ Switch

`Switch[expr, form1, value1, form2, value2, ...]` evaluates *expr*, then compares it with each of the *form_i* in turn, evaluating and returning the *value_i* corresponding to the first match found.

Only the *value_i* corresponding to the first *form_i* that matches *expr* is evaluated. Each *form_i* is evaluated only when the match is tried. ■ If the last *form_i* is the pattern `_`, then the corresponding *value_i* is always returned if this case is reached. ■ If no *value_i* is returned, the final value of the `Switch` is `Null`. ■ You can use `Break`, `Return` and `Throw` in `Switch`. ■ See page 258. ■ See also: `If`, `Condition`, `Which`.
