

■ Through

`Through[p[f1, f2][x]]` gives `p[f1[x], f2[x]]`.

`Through[expr, h]` performs the transformation wherever *h* occurs in the head of *expr*.

Example: `Through[(f + g)[x, y]]` $\longrightarrow$ `f[x, y] + g[x, y]`. ■ `Through` distributes operators that appear inside the heads of expressions. ■ See page 246. ■ See also: `Operate`.
