

■ Together

`Together[expr]` puts terms in a sum over a common denominator, and cancels factors in the result.

Example: `Together[1/x + 1/(1-x)]` $\longrightarrow -\left(\frac{1}{-x+x}\right)$. ■ `Together` makes a sum of terms into a single rational

function. ■ The denominator of the result of `Together` is the lowest common multiple of the denominators of each of the terms in the sum. ■ `Together` is effectively the inverse of `Apart`. ■ See page 386. ■ See also: `Collect`, `Cancel`, `Factor`.
