

■ TrueQ

`TrueQ[expr]` yields `True` if `expr` is `True`, and yields `False` otherwise.

Example: `TrueQ[x==y]  $\longrightarrow$  False`. ■ You can use `TrueQ` to “assume” that a test fails when its outcome is not clear.

■ `TrueQ[expr]` is equivalent to `If[expr, True, False, False]`. ■ See page 259. ■ See also: `If`, `Condition`, `SameQ`.
