

■ Which

`Which`[$test_1$, $value_1$, $test_2$, $value_2$, ...] evaluates each of the $test_i$ in turn, returning the value of the $value_i$ corresponding to the first one that yields `True`.

Example: `Which[a==b, x, 1==1, y]` $\longrightarrow$ `y`. ■ `Which` has attribute `HoldAll`. ■ If none of the $test_i$ give `True`, `Which` returns `Null`. ■ You can make `Which` return a “default value” by taking the last $value_i$ to be `True`. ■ See page 258. ■ See also: `Switch`.
