

■ AlgebraicRules

`AlgebraicRules[eqns, { $x_1$ ,  $x_2$ , ...}]` generates a set of algebraic rules which replace variables earlier in the list of x_i with ones later in the list, according to the equation or equations *eqns*.

You can use `AlgebraicRules` to set up algebraic transformations which you need to apply many times. ■ The argument *eqns* can be a single equation of the form *lhs==rhs*, or a list of equations {*lhs₁==rhs₁*, *lhs₂==rhs₂*, ...}. ■ `AlgebraicRules` generates an `AlgebraicRulesData` object, which contains a representation of the Gröbner basis for the equations *eqns*. In standard `OutputForm`, the output from `AlgebraicRules` is printed like a list of replacements. ■ You can use *expr/.arules* to apply a set of algebraic rules to a particular expression. ■ See page 410. ■ See also: `Eliminate`, `Replace`.
