

■ Alias

`in` $:=$ `trans` defines an alias, which causes `in` to be textually translated to the symbol `trans` on input. `in` can be either a string, or a symbol name, possibly including context marks.

`Alias["in"]` gives any aliases that have been defined for the string `"in"`.

`Alias[ ]` gives all aliases that have been defined.

Example: `m := Statistics`Mean` specifies that `m` should be textually translated to `Statistics`Mean`. ■ Alias translations are done only on complete symbol names. Defining an alias for `m` does not affect `mm`. ■ Aliases are translated as soon as input is read. They are independent of context, and of evaluation. ■ You can give an alias for any string. `"++" := Increment` defines an alias for `++`. This will not be used in ordinary expressions, but will be retrieved if you type `?++`. ■ See page 305. ■ See also: `UnAlias`.
