

■ 1.3.5 Sequences of Operations

You can type in a sequence of *Mathematica* operations just by separating them with semicolons. (You can think of the semicolons as like the statement delimiters in languages like C.)

This does three operations on the same line. The semicolons separate different operations.

```
In[1]:= x = 4; y = 6; z = 7
Out[1]= 7
```

If you put a semicolon at the end of your input, *Mathematica* will print no output.

```
In[2]:= x = 8;
```

However, you can always use % to refer to the expression that *Mathematica* would have given as output.

```
In[3]:= %
Out[3]= 8
```

You can think of putting a semicolon at the end of your input as like adding an extra “empty operation”, which yields no output to be printed.

$expr_1; expr_2; expr_3$	do several operations, giving the result of the last one
$expr_1; expr_2;$	do the operations, but print no output

Ways to do sequences of operations in *Mathematica*.
