

■ Options

`Options[symbol]` gives the list of default options assigned to a symbol.

`Options[f[x, y, ..., name1 -> value1, ...]]` gives the options explicitly specified in a particular expression.

Many built-in functions allow you to give additional arguments that specify options with rules of the form *name -> value*.

■ `Options[f]` gives the list of rules to be used for the options associated with a function *f* if no explicit rules are given when the function is called. ■ `Options` always returns a list of transformation rules for option names. ■ You can assign a value to `Options[symbol]` to redefine all the default option settings for a function.

■ `SetOptions[symbol, name -> value]` can be used to specify individual default options. ■ See pages 113 and 564.
