

■ Return

`Return[expr]` returns the value *expr* from a function.

`Return[ ]` returns the value `Null`.

`Return[expr]` exits control structures within the definition of a function, and gives the value *expr* for the whole function.

■ `Return` is effective only if it is generated as the value of a segment in a compound expression, or as the body of a control structure. `Return` also works in `Scan`. ■ See page 260. ■ See also: `Break`, `Throw`.
