

■ TableForm

`TableForm[list]` prints with the elements of *list* arranged in tabular form.

`TableForm[list, d]` puts elements down to level *d* in *list* in tabular form.

`TableForm` prints the elements arranged in an array of rectangular cells. ■ The height of each row and the width of each column are determined by the maximum size of an element in the row or column. ■ Unlike `MatrixForm`, `TableForm` does not require all cells in the table to be the same size, or to be square. ■ `TableForm` prints a single level list in a column. It prints a two-level list as a two-dimensional table. More deeply nested lists are printed with successive dimensions alternating between rows and columns. ■ See page 272. ■ See also: `ColumnForm`, `MatrixForm`.
