

■ Unequal

$lhs \neq rhs$ returns `False` if lhs and rhs are identical.

$lhs \neq rhs$ returns `True` if lhs and rhs are determined to be unequal by comparisons between numbers or other raw data, such as strings. ■ Real numbers are considered unequal if their difference is larger than the precision of either of them.

■ $e_1 \neq e_2 \neq e_3 \neq \dots$ gives `True` only if none of the e_i are equal. $2 \neq 3 \neq 2 \longrightarrow \text{False}$. ■ $lhs \neq rhs$ represents a symbolic condition, that can be generated and manipulated by functions like `FullSolve` and `LogicalExpand`.

■ `Unequal[e]` gives `True`. ■ See page 72. ■ See also: `Equal`, `Order`.
